Abstract: We study how the COVID-19 pandemic changed the valuation of amenities in the prices of short-term rental listings in Mexico, a country that had few tourism and mobility restrictions during the pandemic. Using data on the universe of short-term rental listings in Mexico from 2018 to 2023, we estimate hedonic price models and analyze how their coefficients changed for amenities associated with a lower risk of COVID-19 infection and reduced face-to-face contact. Our results show that the valuation of remote work amenities, such as workspaces, open-space amenities like beachfronts, and reduced-contact amenities, such as private spaces, increased significantly during the pandemic. Some of these valuation changes, such as those for workspaces and elevators, persist in the post-pandemic-restrictions period. The results are consistent with both a changing taste for certain amenities and a change in the demographic composition of short-term rental consumers in Mexico.
Keywords: Hedonic pricing models, COVID-19, tourism, Airbnb
JEL Classification: R21

Resumen: Estudiamos cómo la pandemia por COVID-19 cambió la valoración de diferentes amenidades en los precios de propiedades de alquiler de corto plazo en México, un país que tuvo pocas restricciones al turismo y a la movilidad durante la pandemia. Usando datos del universo de propiedades de alquiler temporal en México de 2018 a 2023, estimamos modelos de precios hedónicos y analizamos cómo cambiaron sus coeficientes para amenidades asociadas con un menor riesgo de infección por COVID-19 y con menor contacto cara a cara. Nuestros resultados muestran que la valoración de amenidades de trabajo remoto, como espacios de trabajo, amenidades de espacios abiertos, como el acceso a la playa, y amenidades de contacto reducido, como espacios privados, se incrementó significativamente durante la pandemia. Algunos de estos cambios de valoración, como los de los espacios de trabajo, persisten en el periodo posterior a las restricciones por la pandemia. Los hallazgos son consistentes tanto con un cambio en las preferencias por ciertas amenidades como con un cambio en la composición de los consumidores de alquiler temporal en México.
Palabras Clave: Modelos de precios hedónicos, COVID-19, turismo, Airbnb

1 Introduction

Few sectors experienced such significant disruptions during the COVID-19 pandemic as the tourism sector. The closure of non-essential businesses and the restrictions on national and international mobility sharply reduced the demand for tourism worldwide. UNWTO (2020) estimates that by the end of 2020, international tourism arrivals were down 74% compared to a year earlier.

Some tourism activity remained despite the significant restrictions. However, the nature of tourism underwent a dramatic change. Short-term rental providers emphasized cleanliness, open spaces, and flexible cancellation options to attract consumers (OECD, 2020). At the same time, consumers began to demand different tourism options and chose different tourist destinations.

We study how the valuation of amenities in short-term tourism rentals changed during and after the COVID-19 pandemic. Our analysis uses data from the universe of Airbnb listings in Mexico –the largest short-term rental online platform. We show that the valuation of amenities related to remote work, open spaces, and reduced probability of contagion increased after 2020. The changes in the valuation of gyms, private pools, and private living rooms were transitory, while those for workspaces, waterfronts, and elevators persisted after pandemic restrictions ended.

Mexico did not restrict national or international air travel during the pandemic, unlike other countries.[1] Land crossings through the Mexico-US border were restricted to essential activities from March 2020 to November 2021. Arguably, due to these differences in regulations, Mexico became an attractive destination for tourists during the pandemic. In 2020, Mexico ranked as the third most visited country in the world, receiving 24.3 million international tourists, whereas from 2017 to 2019, it had ranked seventh.[2]

To obtain amenity valuations, we estimate hedonic price models with the average daily rate per listing as a dependent variable. We consider a wide array of listing features as explanatory variables. These include the listing's amenities, location, and owner's characteristics. The rich dataset enables us to control for neighborhood and municipality-time fixed effects, thereby addressing the effects of unobservable features

[1] The only requirement for air travel was an online health questionnaire. This requirement started in June 2020 (Gobierno de México, 2020).

[2] The ranking is based on data from UNWTO (2025) from 2017 to 2020. To build the ranking, we considered international tourist arrivals (overnight visitors), excluding same-day visitors and cruise excursionists.

at the neighborhood level and time-varying heterogeneity across municipalities. The coefficient estimates are the marginal valuations for the amenities of Airbnb in the sample (Black, 1999; Bayer et al., 2007). Our regressions explain approximately 80% of the variance in the price of Airbnb listings. We evaluate the robustness of our hedonic price estimates to gauge how strong selection on unobservables would need to be to nullify our results. To address composition effects coming from changes in supply, we also calculate valuation estimates using a sample of properties that remained listed throughout the entire analysis period.

Our results show that the marginal valuation of several amenities changed substantially during the pandemic. The valuation of access to a gym, a pool, or a jacuzzi increased. These positive changes are consistent with a higher demand for open spaces and amenities that were unavailable elsewhere due to business closures. However, the higher implicit price for private access to these amenities was only temporary, as businesses eventually reopened. We also find evidence of valuation change related to contagion-avoidance behavior and an increased demand for properties in smaller buildings. Specifically, the valuation for having a private living room on the premises rose, while the valuation for elevators declined. The change in the valuation for elevators persisted during 2023.

The changes in valuation we find are heterogeneous between tourist and non-tourist destinations. In touristic beach municipalities, the value of access to a gym and a waterfront increases the most. In non-touristic places, the hedonic coefficients for workspaces and pools had larger positive changes. These results are consistent with people shifting their workplaces from offices to getaways, either by the beach or away from city centers.

The change in hedonic coefficients may reflect changes in consumers' taste for amenities, changes in consumer composition, or both. We provide descriptive evidence on an increase in flight passenger arrivals to beaches relative to non-beach destinations, which may indicate either an increased utility valuation for beach listings or the entry of consumers with different taste patterns in the tourism market. We also estimate our models on a subsample of cities that are expected to receive fewer international tourists due to travel warnings. While the valuation of gyms and waterfronts increased in both travel-warning and non-travel-warning cities, the hedonic coefficients for laptop-friendly spaces and elevators changed more in places that receive international travel, indicating that the changed valuation for these amenities in the pandemic and post-pandemic-restrictions periods is likely due to changes in the composition of international tourists towards those interested in remote work.

Our work contributes to the literature on the determinants of prices for touristic rentals such as hotel rooms and Airbnb properties. For hotel rooms, Chen and Rothschild (2010) study prices in Taipei using a hedonic pricing model similar to the one presented in this paper. Cai et al. (2019) study the relationship between Airbnb prices and the location of the rental properties, along with host features such as reputation and listing flexibility. Lorde et al. (2019) use a hedonic pricing model to study nightly Airbnb rates in 12 Caribbean countries. Wang and Nicolau (2017) study the prices of Airbnb listings in 33 American and European cities. For Mexico, López Tamayo and Ramírez-Alvarez (2021) analyze the Airbnb market in Mexico City, emphasizing the differences in prices offered by professional vs. non-professional hosts. Examining the determinants of the prices of tourist short-term rentals is crucial for enhancing our understanding of tourism and service inflation.

We emphasize how amenity valuations changed during the pandemic and whether the arrival of SARS-CoV-2 induced temporary or permanent alterations in consumers' valuations of amenities in the short-term house rental market in Mexico. The Mexican case is particularly relevant due to the relatively mild restrictions on tourism in Mexico compared to those in other countries. Other papers have examined these changes in tourism and amenity valuation. Benítez-Aurioles (2024) shows decreased supply, demand, and prices for Airbnb during the pandemic across several cities. Studies about amenities are limited to more specific cases. Hidalgo et al. (2022) shows that the valuation of listings with kitchens in Madrid increased during the pandemic, while the valuation of larger properties decreased. Llaneza and Raya (2021) show how prices in Airbnb listings dropped substantially during the pandemic in Barcelona. Other studies focus on listing features instead of amenities. Lin and Chen (2021) argue that hotels with scenic views and belonging to international chains experienced fewer income losses than other hotels in Taiwan. Bode et al. (2021) show that the pandemic reduced the prices of entire homes on the Airbnb platform and that more experienced hosts did not reduce their prices as much as other hosts. Filieri et al. (2023) examine whether the preferences for entire homes in Airbnb changed during the pandemic in Italy. Ding et al. (2025) show that guest reviews emphasized hygiene and flexibility during COVID, and that these changes in review topics seemed to persist after the pandemic.

We also contribute to the recent urban economics literature on the impact of the pandemic on the valuation of urban amenities and the changes in residential and work locations (Gupta et al., 2022; Rosenthal et al., 2022; Brueckner et al., 2023; Delventhal et al., 2022). Specifically, we demonstrate increases in the valuation of work-related

amenities in Airbnb rental properties, which may be attributed to the shift of workers from offices to working from Airbnb locations.

The rest of the paper proceeds as follows. Section 2 describes the Airbnb listings dataset we use and provides some facts about the Airbnb market in Mexico during the pandemic. Section 3 describes the empirical strategy. Section 4 presents our results on amenity valuation in Airbnb listings, before, during, and after pandemic restrictions. Section 5 provides descriptive evidence of changes in tourist composition. Last, section 6 concludes.

2 Data and Descriptive Statistics

Airbnb data. We use monthly data on Airbnb listings in Mexico collected by AirDNA. The data contains listing-level information on the number of reservations, availability, prices, and characteristics of each Airbnb listing. We restrict our analysis to the period from January 2018 to December 2023.[3] The data covers 26,336 neighborhoods in 1,391 municipalities in the country.

Our outcome of interest is the monthly average daily rate (ADR) for each Airbnb listing. The ADR is the total monthly income for a listing divided by the number of occupied nights.[4] We convert all prices to Mexican pesos of August 2018.

The explanatory variables are a large set of listing characteristics. We list them in Table 1. Following Faye (2021), Cai et al. (2019), López Tamayo and Ramírez-Alvarez (2021), and Lorde et al. (2019), we classify them in four groups: intrinsic attributes, convenience attributes, reputation attributes, and environmental variables. Intrinsic attributes correspond to listing features, including listing amenities. Among these amenities, there are dummy variables for the presence of a pool, a gym, or a workspace, as well as kitchen amenities, shared spaces, and security features. We also include the number of bedrooms and bathrooms in the property, as well as dummy variables for listing types (e.g., private room, entire residence).

Convenience attributes include features that make reservations easier for customers, such as low fees for additional guests, minimal security deposit amounts, and flexible

[3] We restrict the beginning of the analysis period to 2018 to omit changes in valuation that may be due to additional municipalities entering the dataset. Between 2015 and 2018, the sample of municipalities expanded due to Airbnb's rapid growth nationwide.

[4] We exclude listings in the bottom and top 1% of the distribution of prices in each state to remove outliers. The ADR figures include cleaning fees, if applicable. Airbnb hosts sometimes adjust prices through cleaning fees instead of changing the listing price per night (Dogru et al., 2021).

Table 1: Variables and Description

Category	Variable	Type	Description
Dependent variable	ADR	Continuous	Average daily rate. Includes cleaning fees
Intrinsic attributes	Entire home, private room, shared room	Dummies	Listing types
	Single family home, multifamily home, villa, dorm or hostel, hotel or resort	Dummies	Property types
	Bedrooms	Continuous	Number of bedrooms
	Bathrooms	Continuous	Number of bathrooms
	Gym, cable, ac, hot water, workspace, pool or jacuzzi, tv, wifi, garden or backyard, patio or balcony, pets allowed, kitchen, free parking, elevator, waterfront, breakfast, coffee machine, bbq area, doorman, crib, host checkin, room shades, bathtub, toys, gas detector, washing machine, dryer, oven, bed linens, cooking basics, dishwasher, stove, bedroom door lock, hot tub, refrigerator, dishes, fire extinguisher, family friendly, private living room, heating, high chair, hair dryer, hangers, iron, private entrance, smoke detector, extra pillows, first aid kit	Dummies	Amenities offered in the listing
Convenience attributes	Maximum guests	Continuous	Maximum number of guests allowed
	Extra people fee	Continuous	Extra people fee chosen by the host
	Security deposit	Continuous	Security deposit chosen by the host
	Minimum stay	Continuous	Minimum nights of stay
	Exact location	Dummy	Exact coordinates of the property are shown on the platform
	Instant book	Dummy	The property can be booked without needing the host's approval
	Flexible-moderate, firm-strict, superstrict, luxe policy	Dummies	Cancellation policy chosen by the host is Flexible or Moderate, Firm or Strict, Super Strict 30 or 60 Days, or for Luxe stays
Reputation attributes	Seniority	Continuous	Length (in months) since the listing was created on the platform
	Num of photos	Continuous	Number of photos displayed on the platform
	Num of reviews	Continuous	Number of listing reviews
	Response rate	Continuous	Percentage of inquiries and requests a host answers in a day
	Superhost	Dummy	The host has superhost status
	Professional	Dummy	The host has two or more listings on the platform
	Overall rating	Continuous	Average guest rating of the overall experience
Environmental variables	Beach destination	Dummy	The property is located in a top beach destination
	Competition	Continuous	Number of listings in the same neighborhood allowing the same maximum number of guests
	Dist centroid	Continuous	Distance (in km) between the property and the municipality's centroid calculated using the Harversine formula
Pandemic variables	Pre-pandemic, pandemic and post-pandemic	Dummies	The reporting month is before, during or after the pandemic of COVID-19
	Exited, entered, stable	Dummies	The listing is observed only before or after the pandemic; or else, in both periods

Source: AirDNA, author's classification.

cancellation policies. Reputation attributes are listing and host characteristics associated with higher reliability. These include listing tenure and host ratings.[5] The last set of attributes we include is those related to the listing's location, such as its distance

[5] We classify the listings with missing values in the Superhost, Exact location, and Instantbook dummy variables as not having the attribute. We also considered observations with missing values on the "Extra people fee" and "Security deposit" variables as not charging these additional fees. We made these substitutions after consulting with AirDNA to ensure we were not misinterpreting the data.

to the center of the municipality, whether it is on a beach destination or not, and the degree of competition it faces, as measured by the density of Airbnb listings in the area.[6]

Tourism and the Airbnb market before and during the pandemic. Tourism is one of the main economic activities in Mexico. It accounted for 8.6% of GDP in 2023 and 7.2% of salaried employment (INEGI, 2024). The country is among the ten most-visited countries in the world (UNWTO, 2021). Airbnb is a large player in the tourism market: since 2018, Airbnb has accounted for more than one-fifth of available rooms in the country, including hotel rooms (Banco de México, 2021).

Although both hotel rooms and Airbnb reservations declined substantially at the beginning of the pandemic, recovery in the Airbnb market was faster than in the hotel room market. Banco de México (2021) estimates that reservations in hotels and Airbnb in April 2020 were at 28% and 4% of their pre-pandemic levels. However, by March 2021, the Airbnb market had recovered to its pre-pandemic level, while hotel room reservations were still at half the level of February 2020.

Figure 1 shows the evolution of Airbnb listings in Mexico during our study period. We separate our analysis into three periods: the "pre-pandemic period" from January 2018 to February 2020, the "pandemic-restrictions" period from March 2020 to April 2022, and the "post-pandemic-restrictions" period from May 2022 to December 2023.[7] Our sample includes 1,680,917 listings in the pre-pandemic period, 1,762,057 during the pandemic and 1,844,180 listings in the post-pandemic-restrictions period. The impact of the pandemic on the number of listings is visible from its outset, but the recovery in listings was swift.

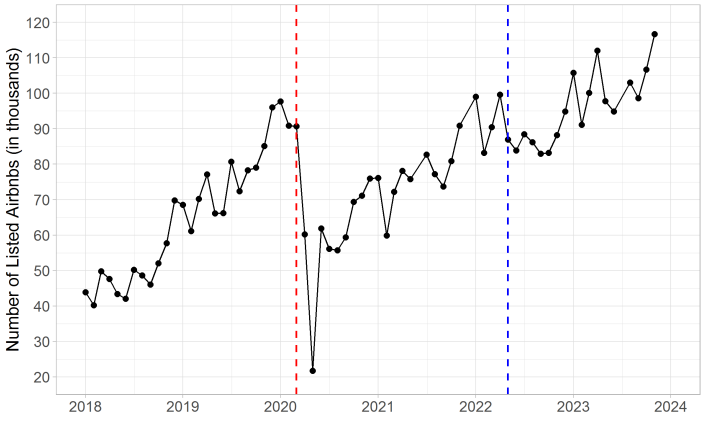

Table 2 shows descriptive statistics of selected features of the listings in the pre-pandemic, pandemic-restrictions, and post-pandemic-restrictions periods.[8] The pandemic changed listing features associated with a reduced probability of contagion. For example, the listings where the host personally helped the guest check in decreased from 36% to 21.4%. At the same time, the percentage of listings with private entrances increased by ten percentage points (p.p.). Entire residence rentals gained about 6%

[6] The beach municipalities are Acapulco, Campeche, Cancún, Cozumel, Huatulco, Isla Mujeres, Ixtapa Zihuatanejo, La Paz, Loreto, Los Cabos, Manzanillo, Mazatlán, Nuevo Vallarta, Playa del Carmen, Puerto Vallarta, Rosarito, Puerto Escondido, Tampico, Tulum, and Veracruz.

[7] We selected this start date for the post-pandemic-restrictions period as it was when Mexican officials stopped posting the COVID-19 Traffic Light Monitoring System, implying that sanitary and mobility restrictions were completely lifted country-wide (El Financiero, 2022).

[8] Appendix Table A.1 shows descriptive statistics for the full set of features.

Figure 1: Evolution of Airbnb listings in Mexico

Source: AirDNA, author's calculation. The first vertical line (red) is in March 2020. The second vertical line (blue) is in May 2022.

of the market share in the pandemic, whereas private rooms in shared properties and shared rooms saw a decrease in market share. This increased share contrasts with the findings for Italy of Filieri et al. (2023), who do not find an increased preference for entire homes during the pandemic in Italy. We also see an increase in host flexibility during the pandemic restrictions period and afterwards, reflected in a fall in the share of listings with strict cancellation policies and a decrease in the average security deposit.

Many of the changes induced by the sanitary crisis disappeared during the post-pandemic-restrictions period. Airbnb suspended its relaxed cancellation policies, so during this period, the share of properties with a strict or super-strict policy increased.

In Figure 2, we look at how the relative amenities supply among listings changed after the pandemic. We focus on a group of amenities related to remote work, preferences for open space, and reduced contagion probabilities. We do not see sharp changes in the relative availability of these selected amenities at the onset of the pandemic. By the beginning of 2021, we observe a decrease in the share of listings with elevators. The share of active listings with elevators decreased from 16.5% in January 2020 to 13.8% in January 2021. By mid-2023, however, this share reverts to 2019 levels.

In contrast, we observe an increase in the availability of listings with gyms, which rose from 11.1% of listings to 11.9% in the same period and continued to rise, reaching 13.1% by the end of 2023. Regarding the post-pandemic-restrictions period, we observe a stable share of active listings offering most amenities, with two exceptions. There is a sharp decrease in the share of listings with "laptop-friendly" spaces, because this amenity was relabeled to "dedicated workspace" in January 2023. The "private living

3 Empirical strategy

This section describes the hedonic price modeling strategy we employ to estimate the valuation of amenities in Airbnb listings, both before and during the pandemic. We estimate log-linear regressions to explain the average daily rate (ADR) using a rich set of Airbnb amenities. Our detailed dataset enables us to use neighborhood and municipality-time fixed effects to mitigate potential omitted variable bias resulting from neighborhood- and municipality-level unobservables.

Our regression specification is the following:

$$\ln P_{ijt} = X'_{ijt}\beta + \gamma Competition_{jt} + \delta_j + \tau_{n(j)t} + \theta_t + \epsilon_{ijt}. \tag{1}$$

Here, $\ln P_{ijt}$ is the log of the ADR for listing i, located in neighborhood j at time t. We observe these prices at a monthly frequency. The matrix X includes listing characteristics. $Competition_{jt}$ is the competition faced by each property, measured as the number of Airbnb listings in the neighborhood with the same maximum number of guests allowed.

We include three groups of fixed effects to account for possible bias arising from omitted variables and unobservables. The parameters θ_t are time fixed effects that account for country-wide changes in Airbnb nightly prices. Another set of parameters, $\tau_{n(j)t}$, measures time-varying unobservables at the municipality level. They also capture seasonal patterns in tourism demand (Juaneda et al., 2011): beach municipalities will have higher demand and prices during the summer months.[9] The parameters δ_j are neighborhood fixed effects. The error term is the variable ϵ_{ijt}. We allow it to be correlated across listings in the same neighborhood over time, so we cluster our standard errors at the neighborhood level.

The coefficients β measure the marginal valuation of each amenity (Rosen, 1974; Black, 1999; Bayer et al., 2007). By including fixed effects at the municipality-time level, we only use variation in listing prices from listings within the same municipality to estimate these marginal valuations β. Our identification assumption is that conditional on these fixed effects plus the effects δ_j, the amenity variables X_{ijt} are uncorrelated with the error term. This assumption may be untenable if there are remaining unobservables in equation (1), or if individuals sort across Airbnb listings (Bayer et al., 2007; Faye, 2021; Jang et al., 2021). We argue that our models have high explanatory power, so any remaining unobservables are unlikely to change the coefficients by a large amount (Oster, 2019).

We estimate equation (1) for the pre-pandemic, pandemic restrictions, and post-pandemic-restrictions periods and separately for beach and non-beach municipalities. To evaluate whether the marginal valuation changed during the pandemic and post-pandemic periods, we test whether the coefficients β differ across these periods. We also estimate equation (1) across quarters to see how the marginal valuation of amenities evolves.

Changes in prices associated with an amenity may not be due to changes in the tastes of tourists, but rather to shifts in the supply composition of Airbnb listings. Indeed, Figure 1 shows that the number of listings changed substantially at the beginning of the pandemic. Banco de México (2021) shows that the supply of listings changed during the pandemic, with hosts offering more amenities related to cleaning and remote work. Moreover, the relative supply of amenities such as gyms, elevators, and pools changed during the pandemic, as shown in 2. To control for these supply composition changes, we also estimate equation (1) on a sample of "stable" listings that appear on the platform

[9] These municipality-time effects $\tau_{n(j)t}$ are not perfectly collinear with the country-wide time effects θ_t because the set of municipalities in the sample changes in some months.

at least once before and during the pandemic restrictions period. While the valuation of amenities in these listings may differ from the valuation of amenities in the overall listing sample, the evolution of valuation over time allows us to examine changes in the equilibrium price premium across listings while isolating changes in supply composition.

4 Results

This section shows our results about the changing valuation of amenities during the pandemic restrictions and post-pandemic-restrictions periods from the estimation of equation (1).[10] First, we show estimates pooling all the observations within each period. These estimates show that the valuation of amenities related to working from home, access to open spaces, and reduced contact increased during the period of pandemic restrictions. We also show quarter-by-quarter estimates, highlighting that the valuation changes begin precisely at the start of the pandemic restrictions and appear to persist during the recovery. Lastly, we show how the valuation changes differ between beach and non-beach municipalities.

Pre-pandemic, pandemic restrictions, and post-pandemic-restrictions estimates. Table 3 shows estimates of the percentage contribution to the ADR, $e^{\beta} - 1$ from estimates of β using equation (1) for the complete sample.[11]

Column (1) from Table 3 shows that at the national level, five out of the six selected amenities had a statistically significant effect on the prices of Airbnb listings before the pandemic. Listings with a gym or a pool were, respectively, 5.8% and 35.2% more expensive than other listings. Elevators and access to a waterfront also positively affected listing prices. On the other hand, the presence of a "laptop-friendly workspace" had a slight negative impact on the listing price.[12] This finding coincides with that of Faye (2021) and may be due to consumers perceiving these listings as more cramped. Another possible reason why the valuation for elevators decreased noticeably may be

[10] We use the R package "fixest" from Bergé (2018) for all the estimations.

[11] The coefficients can also be interpreted as the change in nightly revenue for hosts whose properties include the amenities, and thus understood as a change in the producer surplus for hosts with listings that have each amenity keeping fixed costs constant.

[12] This amenity is frequently misunderstood among hosts and guests. The misunderstanding may explain why Airbnb changed the term from "laptop-friendly workspace" to "dedicated workspace" in recent years (Airbnb Community Center, 2021). According to Airbnb (2022), hosts offering a dedicated workspace do not need to provide a separate room for it. However, they must provide a desk, access to a power outlet, and a comfortable chair. Nevertheless, discussions about the interpretation of this amenity remain common, as hosts do not always meet guests' expectations of what constitutes a dedicated workspace (Airbnb Community Center, 2020).

Source: AirDNA, author's calculations. The numbers are estimated percentage contributions to the ADR of each amenity. "Pre-pandemic" estimates are for January 2018 - February 2020. The "Pandemic restrictions" estimates are for March 2020 - April 2022. The "Post-pandemic-restrictions" estimates are for May 2022 - December 2023. Standard errors clustered at the neighborhood level in parentheses. "Diff" columns correspond to the difference in the coefficients between periods. The p-value for a test of whether these differences are zero is reported in brackets. The omitted categories for listing type, property type, and cancellation policy are entire home, single-family home, and flexible-moderate, respectively. *p<0.1; **p<0.05; ***p<0.01. † For Private living room, the "Post-pandemic-restrictions" estimates are for May 2022 - December 2022.

a change in the demographic composition of visitors to Mexico. Using data from the Survey of International Travelers Leaving the United States (U.S. Department of Commerce, National Travel and Tourism Office, 2025), we estimate that the mean age of visitors from the United States to Mexico dropped from 46.5 years for both genders in October 2019 to 41.5 years for women and 43.2 years for men in October 2021.

Amenity valuations during the pandemic-restrictions and post-pandemic-restrictions periods appear in columns (2) and (3), respectively. We also show the differences in valuation between periods. During the pandemic restrictions period, the value for a workspace increased by around 1.2 p.p., consistent with an increasing demand for listings for remote work. This increased hedonic coefficient for a workspace persisted in the post-pandemic-restrictions period, possibly because some work-from-home schemes remained in place after COVID-19. The valuation of waterfront properties during the pandemic restrictions and post-pandemic-restrictions periods increased by 2.4 p.p. and 2.7 p.p., respectively. We also observe changes in amenity values consistent with the expected increase in willingness to pay for reduced contact with other people. Since gyms were closed at the beginning of the pandemic, and presumably because attending a large gym may involve a risk of SARS-CoV-2 contagion, customers increased their valuation for access to a gym. They also reduced their willingness to pay for listings with elevators and increased it for those with private living rooms. The increased value of gyms occurs despite an increase in relative availability, suggesting that this increase may have stemmed from a supply reaction late in the pandemic, driven by larger demand. In the post-pandemic-restrictions period, as large gyms eventually resumed activities and COVID-19 restrictions for businesses eased, the change in their hedonic coefficient reverted.

Table 4 shows estimates separating the beach and non-beach municipalities. Columns (4) to (9) show the valuation of amenities in beach municipalities and non-beach municipalities. There is a higher perceived value for gyms and waterfronts in beach destinations relative to non-beach destinations. For example, before the pandemic, access to a gym was associated with a listing price 11.4% higher in beach destinations. In contrast, it marginally reduced listing prices in non-beach municipalities.

During the pandemic restrictions period, the valuation of gyms increased by 2.6 p.p. relative to before in beach municipalities, but it did not have a statistically significant change in non-beach areas. Access to a pool or a jacuzzi became more valuable during the pandemic in non-beach destinations, but not in beach destinations. This difference between beach municipalities and the rest is consistent with an increase in the valuation

of open spaces in places where they were not widely available. The increased valuation during the pandemic for pools and jacuzzis in places without tourist beaches showed the same pattern as gyms in beach municipalities. As public or shared pools and jacuzzis reopened and people gradually became more comfortable around others, the higher perceived value for private pools and jacuzzis was not sustained.

Quarterly estimates. Figure 3 shows results of estimating equation (1) separately for every quarter. These calculations illustrate how the estimates of amenity valuations change over time. For gyms, elevators, waterfronts, and private living rooms, the time series of the estimated coefficients show a stable valuation in the pre-pandemic period and a clear change in trend that coincides with the beginning of the pandemic. Evidence for changes in the valuation trend for workspaces, pools, or jacuzzis is less clear than for other amenities. However, there are clear differences in the averages between the pandemic and pre-pandemic periods.

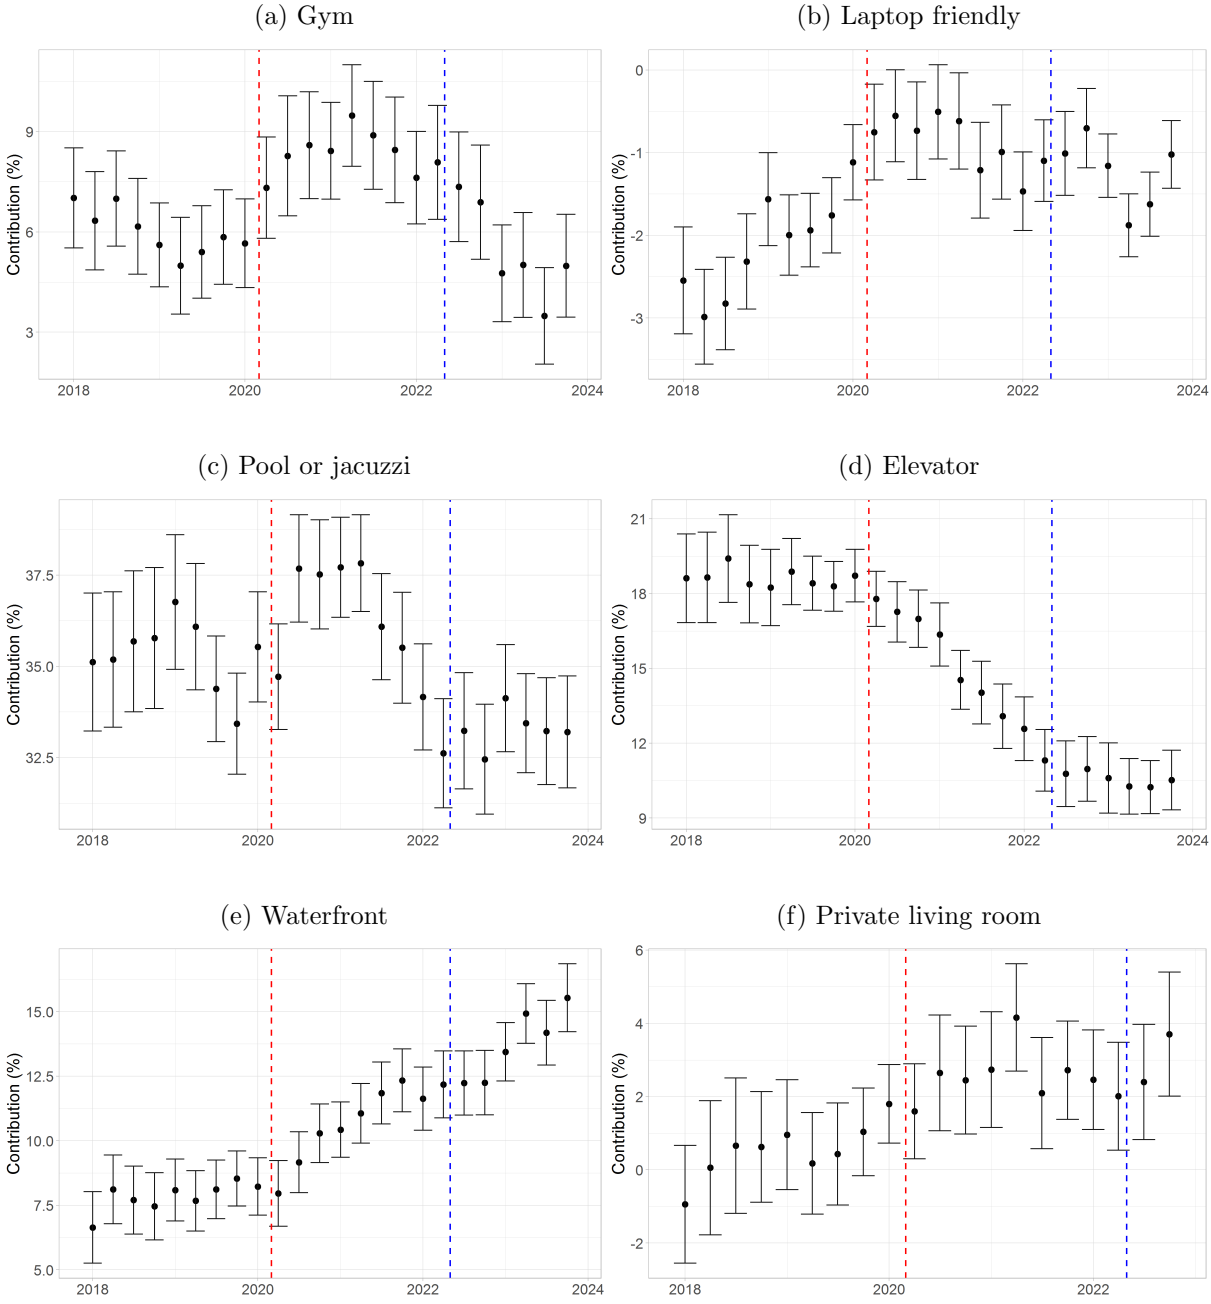

We also estimate quarterly specifications for beach and non-beach municipalities in Appendix Figures A.1 and A.2. The heterogeneity in the time evolution of the coefficients for beach and non-beach municipalities follows the patterns shown in Table 4. The changes in valuation for gyms and waterfronts in the pandemic are noteworthy in beach municipalities but not evident in non-beach municipalities. Valuation for pools and jacuzzis shows a trend change at the beginning of the pandemic, only for non-beach places.

Robustness. We conduct two additional exercises to gauge the robustness of our results.[13] First, we re-estimate equation (1) on a sample of stable listings observed at least once in the pre-pandemic period and once in the post-pandemic-restrictions period. These estimates avoid valuation changes resulting from supply shifts caused by the changing composition of Airbnb listings, particularly in the first months of the pandemic. Appendix Table A.3, shows the full results for the complete and restricted stable listings from the national sample, A.4 from the beach sample, and A.5 from the non-beach sample. The changes in amenity valuations are similar across samples. These results suggest that the changes in valuation we observe are not due to the change in the percentage of listings that offer each amenity type during the pandemic.

We also estimate equation (1) on a restricted period starting in 2019, rather than 2018. We do this because Figure 3 shows that the time series of amenity valuations does show lower levels for some amenities in 2018, raising concerns about trending unobservables. Table A.2 in the Appendix shows that amenity valuations still exhibit

[13] We acknowledge that changes in amenity coefficients could also be influenced by host professionalism. We ran separate regressions for Superhosts and non-Superhosts. Results indicate that most amenities (elevator, private living room, and pool) show consistent patterns across host types. Laptop-friendly shows no effect for Superhosts, potentially reflecting that its value is overshadowed by broader indicators of host quality such as Superhost status itself. Gym valuation declined for Superhosts at the start of the pandemic, probably due to actual gym closures communicated more transparently by professional hosts. These results suggest that the changes in amenity coefficients are not likely influenced by host quality.

Figure 3: Effect of amenities on log average daily rate of Airbnb listings for selected amenities. Quarterly estimates, national sample

Source: AirDNA, author's calculations. The points are percentage contribution estimates of 3-month windows analogs of equation (1). The vertical bars are 95% confidence intervals. Standard errors clustered by neighborhood. The first vertical line (red) marks the beginning of the pandemic. The second vertical line (blue) marks the beginning of the post-pandemic-restrictions period. For Private living room, the "Post-pandemic-restrictions" estimates are for May 2022 - December 2022.

statistically significant changes in this estimation with a more limited pre-pandemic period.

Biases from unobservable selection. Because our hedonic price models estimate the effects of several attributes on Airbnb prices without quasi-experimental variation, a valid concern is that unobservables may be driving our results. To address this issue, we follow Oster (2019) and calculate statistics indicative of how serious the bias from unobservables needs to be to invalidate our results under a proportional selection assumption.

In Table 5, we show coefficients from equation (1) without and with fixed effects by neighborhood and municipality time, along with the R-squared values for both regressions. We do this for the pre-pandemic and pandemic periods. Then, we calculate the degree of selection in unobservables needed to drive these valuation coefficients to 0.[14,15].

In the pre-pandemic period, for the valuation of gyms to be 0, unobservables would need to bias the coefficient in the opposite direction as the bias accounted for by the fixed effects, and would need to be almost twice as important as the unobservables captured by fixed effects. In the pandemic restrictions period, unobservables would need to be nine times as important as observables in determining the variance of prices. In the post-pandemic-restrictions period, they would need to be 1.5 times as important as the unobservables to drive the valuation of gyms to zero. Our results for the valuation of pools and elevators, particularly for beach municipalities, are also robust to unobservable selection. We also provide bounds on the coefficient estimates, assuming that unobservables are as important as observables.

In the middle panel, we also show the degree of selection in unobservables needed for the pandemic restrictions period, for coefficients equal to their pre-pandemic estimated counterparts. This test is imperfect because the pre-pandemic coefficient estimates may be biased themselves. Nevertheless, our findings for several of the amenities are robust. At the national level, omitted time-varying unobservables would need to be about as important as observables, or would need to change the direction of the bias, to rule out changes in the valuation of gyms, workspaces, and elevators.

The bottom panel shows the degree of selection in unobservables required for the

[14] We use the R package "robomit" from Schaub (2021) to compute the estimates. We exclude private living rooms from this calculation because of the limited post-pandemic-restrictions period.

[15] We use Oster's approach $R_{max} = \min(2.2R^*, 1)$, where R^* is the R-squared of the estimation with fixed effects (González and Miguel, 2015).

Source: AirDNA, author's calculations. Column "No-FE" shows estimates from (1) without neighborhood and municipality-time fixed effects. Column "FE" shows estimates including fixed effects. "Sel. for coef = 0" shows the degree of unobservable selection needed for the true coefficient to be 0, assuming proportional selection. A value of 1 implies that unobservables need to be as important as observables in determining the variance of the dependent variable. Column "Bound" shows the coefficient estimate assuming that unobservables are as important as observables. The "Sel. for coef = Pre" column shows the degree of selection on unobservables needed for the pandemic restrictions coefficients to be equal to their pre-pandemic estimates. The "Sel. for coef = Pand" column shows the degree of selection on unobservables needed for the post-pandemic-restrictions coefficients to be equal to their pandemic estimates.

post-pandemic-restrictions coefficients to equal their pre-pandemic and restrictions period estimated counterparts. For amenities whose valuation reverted in the post-pandemic-restrictions period, such as gyms, the selection in unobservables would have to be as severe as accounted for by the observables for the coefficients to be equal to their pre-pandemic values. For other amenities, however, the findings remain robust. For example, time-varying unobservables would need to be more important than unobservables or to change the direction of the bias accounted for by the fixed effects to rule out changes in the valuation of pools and elevators at the national level.

5 Changing taste or changing tourist composition?

So far, we have shown that the valuation of remote work, open space, and reduced-contagion-related amenities in Airbnb listings in Mexico changed during the pandemic. Nevertheless, we cannot argue whether the changes in the hedonic coefficients stem from changing tastes or a shift in the composition of tourists who search for short-term rentals.

There are several reasons to expect that the composition of Airbnb customers and the characteristics of the average Airbnb consumer changed during the pandemic. First, there is anecdotal evidence of increased tourism from the United States to Mexico because of the relatively lax COVID-19-associated restrictions (Glusac, 2021). Second, the pandemic may have led to a different type of tourism, as infra-marginal and infrequent short-term property renters decided to do so to avoid contagion and mobility restrictions in cities. For example, reports from Airbnb suggest that the customer base changed from young people to entire families (Meyers, 2021). Third, as documented in the urban economics literature (Rosenthal et al., 2022; Gupta et al., 2022), the pandemic led to an increase in remote work, with remote workers taking advantage of short-term rentals. Without repeated observations by individual, statistics on the demographic characteristics of Airbnb customers, or explicit modeling of heterogeneous preferences, we cannot disentangle the effect of changes in taste for the same consumer from the effect of composition changes.

In Appendix B, we show some descriptive evidence about the composition of tourism to major destination cities in Mexico. We show that there was a significant decline in international tourism at the onset of the pandemic, but this drop was transitory, and, therefore, any persistent change in hedonic coefficients is unlikely to have been driven

by a change in the ratio of international to national tourists. However, the composition of national and international tourism may have changed. We show that the share of international arrivals to Mexico City is below its pre-pandemic level in the pandemic restrictions and post-pandemic-restrictions periods.

To isolate changes in the composition of international travel, we re-estimate our models, splitting our sample according to travel advisories issued by the U.S. Department of State. We separate the sample into "Alert states", which contain places with "do not travel" advisories at any point during our analysis periods, and states with lower warning levels ("reconsider travel", "exercise normal precautions", and "exercise increased caution"). We argue that if taste changes led to changes in the hedonic coefficients and these are not just due to changes in customer composition, then the hedonic coefficient changes should be present even in alert states that tend to receive fewer international tourists.

Table 6 shows the results of these separate estimations. The results show heterogeneous patterns in the change of hedonic coefficients between travel-alert and non-travel-alert states. For example, the increased valuation for laptop-friendly listings occurs exclusively in the non-travel-alert states, and the difference in the valuation increase between groups of states is statistically significant. This pattern of coefficients suggests that some of the increased valuation for laptop-friendly spaces may have been due to a change in the composition of international travelers. In contrast, in places without travel alerts, the hedonic coefficient for pools dropped sharply in the post-pandemic-restrictions period. These patterns may be consistent with newer international travelers having additional willingness to pay for work-related-amenities in Airbnb listings compared to pre-pandemic international travelers.

Source: AirDNA, author's calculations. The numbers are estimated percentage contributions to the ADR of each amenity. "Pre-pandemic" estimates are for January 2018 - February 2020. The "Pandemic restrictions" estimates are for March 2020 - April 2022. The "Post-pandemic-restrictions" estimates are for May 2022 - December 2023. "States with travel alerts" refer to states with a "do not travel" travel advisory level from the U.S. Department of State at any point during the analysis period. These states are Colima, Guerrero, Michoacán, Sinaloa, and Tamaulipas. Standard errors clustered at the neighborhood level in parentheses. "Diff" columns correspond to the difference in the coefficients between periods. The p-value for a test of whether these differences are zero is reported in brackets. *p<0.1; **p<0.05; ***p<0.01. † For Private living room, the "Post-pandemic-restrictions" estimates are for May 2022 - December 2022.

For other amenities, however, the valuation increases are similar across alert and non-alert states. Both gyms and waterfronts exhibit similar changes in hedonic coefficients across the three analysis periods. So for these amenities, the valuation changes may be linked to a change in tastes for all Airbnb customers.

6 Concluding remarks

We test if the valuation of amenities in Airbnb short-term rental listings changed in Mexico during the COVID-19 pandemic and if these changes were transitory or permanent. We demonstrate that certain amenities change valuation in patterns consistent with potential effects of shifting preferences for open spaces, remote work, and close-quarters contact. Specifically, we show that the valuation for gyms, waterfronts, pools, workspaces, private living rooms, and elevators displays substantial changes. These valuation changes are heterogeneous across beach and non-beach municipalities. While some of the changes –such as those for elevators and private living rooms– persisted in the post-pandemic period, others –such as those for open spaces– show signs of reverting to their pre-pandemic levels.

Our results are consistent with a shift in the demand for amenities in tourist destinations among Mexico's average short-term rental consumer. While we cannot distinguish between a change in the tastes of the same set of consumers and a change in consumer composition, we present evidence suggesting that the changes in hedonic coefficients for laptop-friendly properties and elevators stem from a changing traveler composition, whereas the changes for gyms and waterfronts reflect changes in preferences. Either way, the shifts in consumer behavior that we observe may have longer-run consequences in the market for touristic rentals. An open question is whether these valuation changes are present in other markets outside Mexico and whether the valuation of amenities in permanent housing or traditional hotel rooms also experiences a permanent change.

Other research designs, such as the estimation of discrete choice models of consumer behavior, as those in Berry et al. (1995); Bayer et al. (2007), are alternative strategies for examining these changing valuations while imposing additional structure on taste variation across consumers, allowing for richer conclusions regarding the effects of sorting.

Source: AirDNA, author's calculations. Columns Pre-pandemic, Pandemic restrictions and post-pandemic-restrictions report the means in every period. The pre-pandemic period goes from January 2018 to February 2020; the Pandemic period goes from March 2020 to April 2022; the Post-pandemic period goes from May 2022 to December 2023. Standard errors of the means are in parentheses. The Diff and SMD columns report the difference and the standardized mean difference between the periods. The p-value for a test of equality of means across periods is reported in brackets. The average daily rate, Security deposit, and extra person fee variables are in real Mexican pesos, using prices from July 2018. Minimum stay variable is the number of nights.

Figure A.1: Effect of amenities on log average daily rate of Airbnb listings for selected amenities. Quarterly estimates, beach municipalities

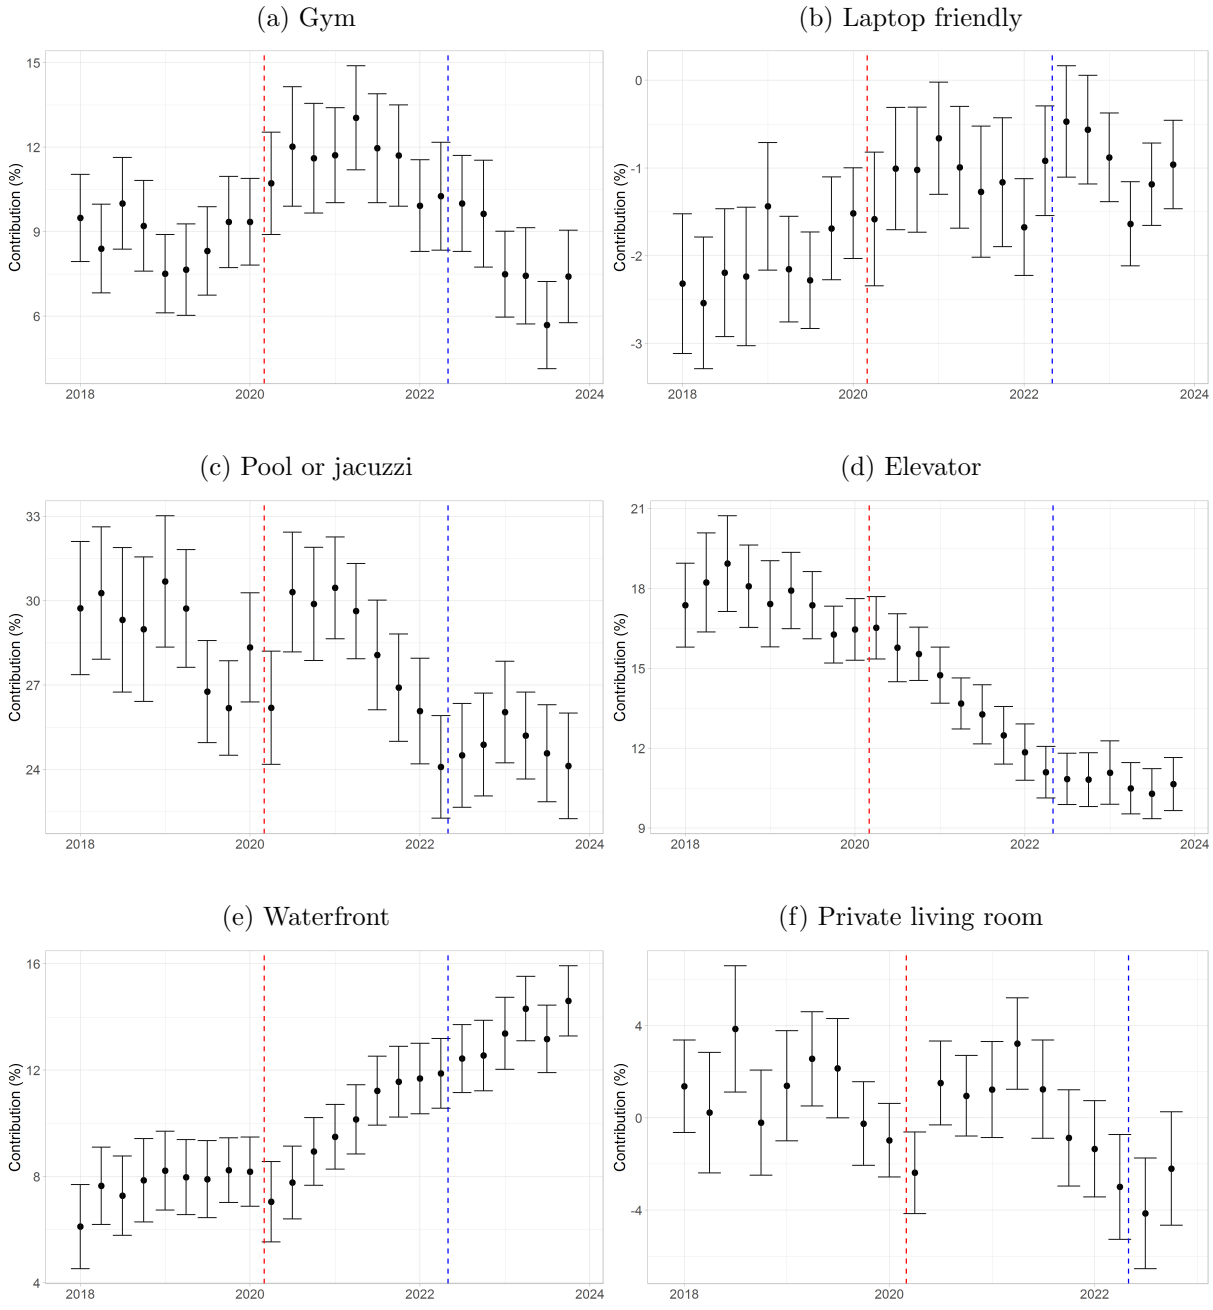

Source: AirDNA, author's calculations. The points are coefficient estimates of a 3-month window analog of equation (1) on the sample of beach municipalities. The vertical bars are 95% confidence intervals. Standard errors clustered by neighborhood. The omitted categories for listing type, property type, and cancellation policy are entire home, single family home, and flexible-moderate, respectively. The first vertical line (red) marks the beginning of the pandemic. The second vertical line (blue) marks the beginning of the post-pandemic period.

Figure A.2: Effect of amenities on log average daily rate of Airbnb listings for selected amenities. Quarterly estimates, non-beach municipalities

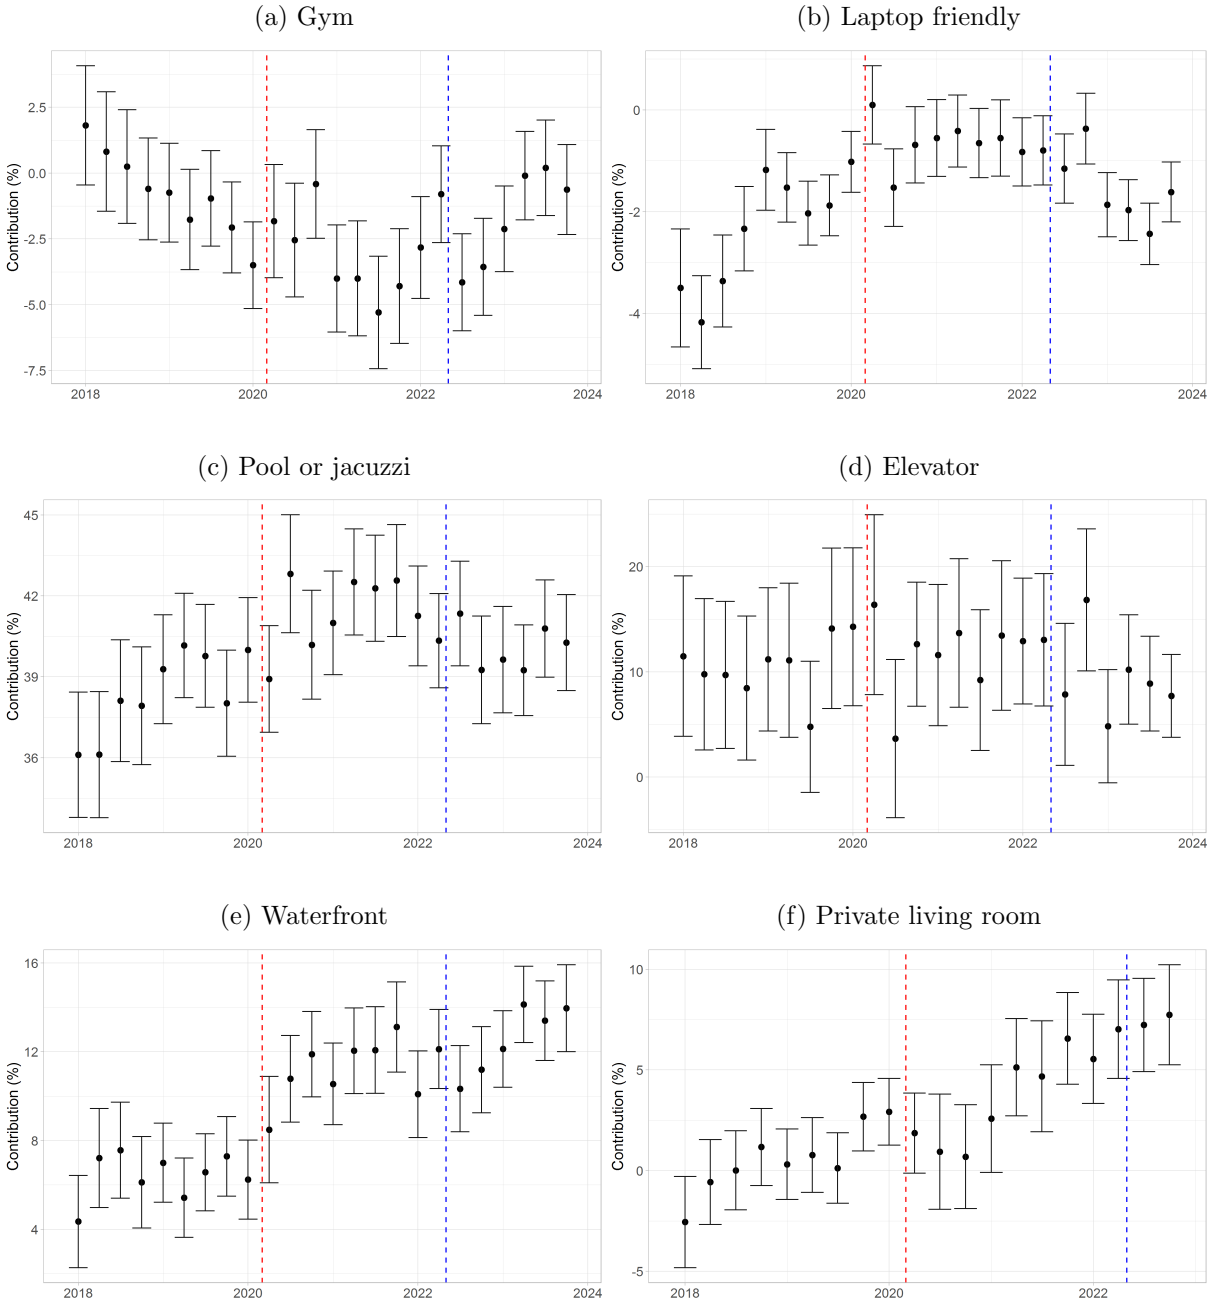

Source: AirDNA, author's calculations. The points are coefficient estimates of a 3-month window analog of equation (1) on the sample of non-beach municipalities. The vertical bars are 95% confidence intervals. Standard errors clustered by neighborhood. The first vertical line (red) marks the beginning of the pandemic. The second vertical line (blue) marks the beginning of the post-pandemic period.

Figure A.3: Effect of amenities on log average daily rate of Airbnb listings for selected amenities. Quarterly estimates, Multifamily home

Source: AirDNA, author's calculations. The points represent coefficient estimates of a 3-month window analog of equation (1) on the sample of non-beach municipalities. The vertical bars are 95% confidence intervals. Standard errors clustered by neighborhood. The first vertical line (red) marks the beginning of the pandemic. The second vertical line (blue) marks the beginning of the post-pandemic period.

Figure A.4: Effect of amenities on log average daily rate of Airbnb listings for selected amenities. Quarterly estimates, Single-family home

Source: AirDNA, author's calculations. The points are coefficient estimates of a 3-month window analog of equation (1) on the sample of non-beach municipalities. The vertical bars are 95% confidence intervals. Standard errors clustered by neighborhood. The first vertical line (red) marks the beginning of the pandemic. The second vertical line (blue) marks the beginning of the post-pandemic period.

Source: AirDNA, author's calculations. The top panel shows OLS estimates of the β coefficients in equation (1) for selected amenities. The bottom panel shows the percentage contribution to the ADR. "Pre-pandemic 2018" estimates are for January 2018 - February 2020. "Pre-pandemic 2019" estimates are for January 2019 - February 2020. The "Pandemic restrictions" estimates are for March 2020 - April 2022. Standard errors clustered at the neighborhood level in parentheses. "Diff" columns correspond to the difference in the coefficients between the pre-pandemic and the pandemic period. The p-value for a test of whether these differences are zero is reported in brackets. The omitted categories for listing type, property type, and cancellation policy are entire home, single family home, and flexible-moderate, respectively. *p<0.1; **p<0.05; ***p<0.01.

B Evidence on changing traveler composition during the pandemic

We provide some descriptive data on traveler composition in Figure B.5. We compile data on flight arrivals by origin and destination from Mexico's Trade and Transportation Department.[16] Panel (a) shows the ratio of international to national flight arrivals in our period of analysis. Before the pandemic, about half of the passengers who landed in Mexican airports came from abroad, and the other half came from flights within the country. The share of international arriving passengers dropped sharply at the onset of the pandemic in 2020. It recovered steadily throughout 2021, except for a brief drop that coincided with a new surge in SARS-CoV-2 contagion. By August 2021, the share of international passenger arrivals was close to pre-pandemic levels.

Suppose the changes in valuation that we document in section 4 were entirely due to an increased share of international customers with different tastes. In that case, we should see a reversal in the trends of the hedonic coefficients in Figure 3 as the share of international passengers returns to pre-pandemic levels. Instead, we see that the trends in the coefficients seem to be persistent, with the possible except those associated with pools in Panel (c). It is possible, however, that the composition of international tourists changed.

In Figure B.5, panel (b), we show that national and international passenger arrivals increased in beach destinations relative to city destinations after the pandemic. The changes persist by the end of our analysis period. This phenomenon would be consistent with a change in consumers' preferences for beach versus non-beach destinations or with a shift in the composition of tourists: customers who did not travel previously may now be traveling to beaches.

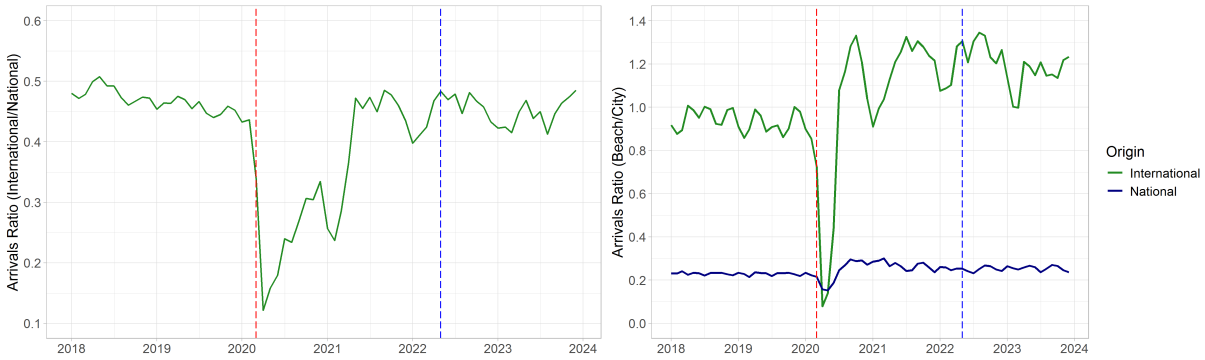

Figure B.6 examines whether there are composition changes in national and international arrivals groups. The Figure shows seasonally-adjusted national and international arrivals at the main airports in both beach and non-beach destinations. Panels (a) and (b) show the share of national arrivals at main airports. During the pandemic, the share of arrivals to Mexico City and other airports fell relative to the share arriving at other destinations, such as Guadalajara or Monterrey. By the post-pandemic period, this compositional change had reverted, but Tijuana had become a more important destination. For beach destinations, there is little evidence of composition change in

[16] We use data on passenger arrivals from commercial, charter, and private flights from Aeropuertos y Servicios Auxiliares, an airport oversight entity affiliated with the Transportation and Commerce Department.

the post-pandemic period relative to the pre-pandemic period in Panel (b).

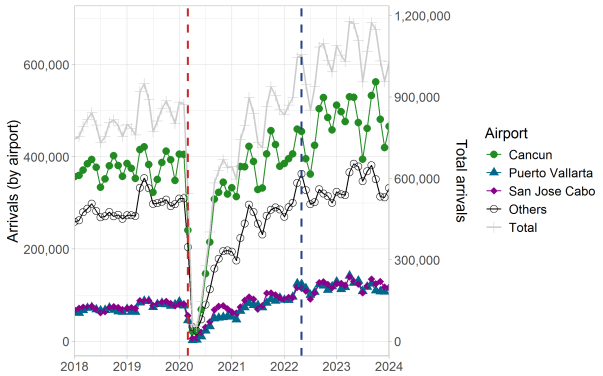

Panels (c) and (d) show international arrivals. The share of arrivals to Mexico City decreased substantially during the pandemic restrictions period and remained depressed relative to other non-beach destinations. Therefore, some of the valuation changes may be due to the different preferences of these consumers traveling to other cities. Panel (d), in contrast, shows that changes in composition of arrivals to beach destinations have largely disappeared in the post-pandemic period.
